Calendar adjustments

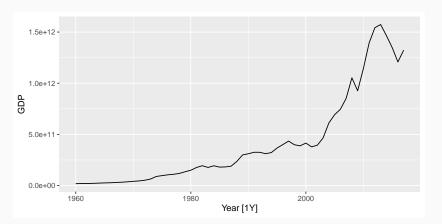

```
as_tsibble(fma::milk) %>%
  rename(total = value) %>%
  mutate(daily_ave = total / days_in_month(as_date(index))) %>%
  pivot_longer(-index, names_to = "Series", values_to = "Milk") %>%
  ggplot(aes(x=index, y=Milk)) + geom_line() +
  facet_grid(Series ~ ., scales='free') + xlab("Year") +
  ylab("Pounds") + ggtitle("Milk production per cow")
```

- 6 Lab Session 7

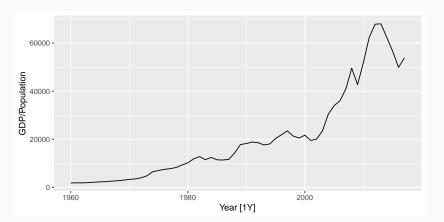

Per capita adjustments

```
global_economy %>%
  filter(Country == "Australia") %>%
  autoplot(GDP)
```

Per capita adjustments

```
global_economy %>%
  filter(Country == "Australia") %>%
  autoplot(GDP / Population)
```

- 4 Inflation adjustments
- 5 Mathematical transformations
- 6 Lab Session 7

Lab Session 6

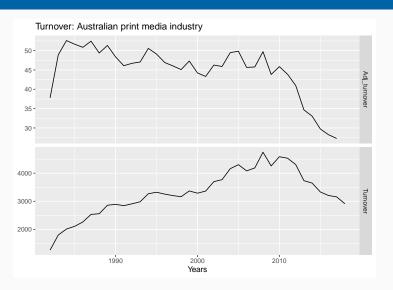

Consider the GDP information in global_economy. Plot the GDP per capita for each country over time. Which country has the highest GDP per capita? How has this changed over time?

- 4 Inflation adjustments
- 5 Mathematical transformations
- 6 Lab Session 7

Inflation adjustments

```
print_retail <- aus_retail %>%
  filter(Industry == "Newspaper and book retailing") %>%
  group by(Industry) %>%
  index_by(Year = year(Month)) %>%
  summarise(Turnover = sum(Turnover))
aus_economy <- filter(global_economy, Code == "AUS")</pre>
print_retail %>%
 left_join(aus_economy, by = "Year") %>%
 mutate(Adj_turnover = Turnover / CPI) %>%
 pivot_longer(c(Turnover, Adj_turnover),
               names_to = "Type", values_to = "Turnover") %>%
  ggplot(aes(x = Year, y = Turnover)) +
    geom line() +
    facet_grid(vars(Type), scales = "free_y") +
    xlab("Years") + ylab(NULL) +
    ggtitle("Turnover: Australian print media industry")
```

Inflation adjustments

- 1 Calendar adjustments
- 2 Per capita adjustments

- 5 Mathematical transformations
- 6 Lab Session 7

If the data show different variation at different levels of the series, then a transformation can be useful.

If the data show different variation at different levels of the series, then a transformation can be useful.

Denote original observations as y_1, \ldots, y_n and transformed observations as w_1, \ldots, w_n .

If the data show different variation at different levels of the series, then a transformation can be useful.

Denote original observations as y_1, \ldots, y_n and transformed observations as w_1, \ldots, w_n .

Mathematical transformations for stabilizing variation

Square root
$$w_t = \sqrt{y_t}$$

Cube root
$$w_t = \sqrt[3]{y_t}$$
 Increasing

Logarithm $w_t = \log(y_t)$ strength

If the data show different variation at different levels of the series, then a transformation can be useful.

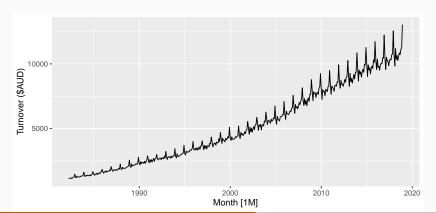

Denote original observations as y_1, \ldots, y_n and transformed observations as w_1, \ldots, w_n .

Mathematical transformations for stabilizing variation

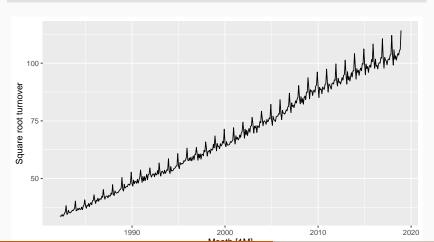

Square root
$$w_t = \sqrt{y_t}$$
 \downarrow Cube root $w_t = \sqrt[3]{y_t}$ Increasing Logarithm $w_t = \log(y_t)$ strength

Logarithms, in particular, are useful because they are more interpretable: changes in a log value are **relative (percent) changes on the original scale**.

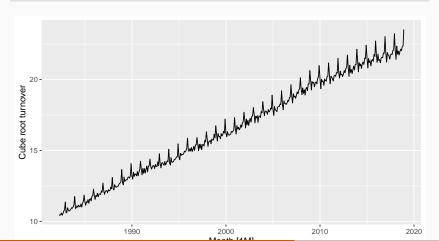

```
food <- aus_retail %>%
  filter(Industry == "Food retailing") %>%
  summarise(Turnover = sum(Turnover))
```

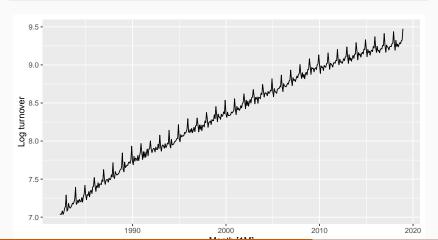

```
food %>% autoplot(sqrt(Turnover)) +
  labs(y = "Square root turnover")
```

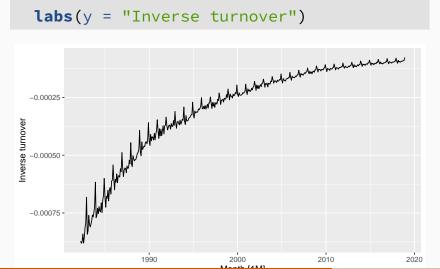

```
food %>% autoplot(Turnover^(1/3)) +
  labs(y = "Cube root turnover")
```

```
food %>% autoplot(log(Turnover)) +
  labs(y = "Log turnover")
```

```
food %>% autoplot(-1/Turnover) +
 labs(y = "Inverse turnover")
```

Each of these transformations is close to a member of the family of **Box-Cox transformations**:

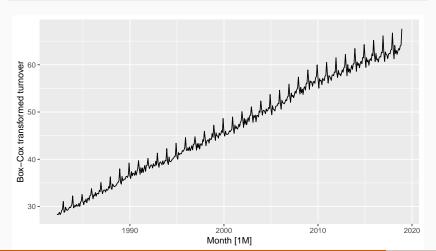

$$w_t = \begin{cases} \log(y_t), & \lambda = 0; \\ (y_t^{\lambda} - 1)/\lambda, & \lambda \neq 0. \end{cases}$$

Each of these transformations is close to a member of the family of **Box-Cox transformations**:

$$w_t = \begin{cases} \log(y_t), & \lambda = 0; \\ (y_t^{\lambda} - 1)/\lambda, & \lambda \neq 0. \end{cases}$$

- λ = 1: (No substantive transformation)
- $\lambda = \frac{1}{2}$: (Square root plus linear transformation)
- λ = 0: (Natural logarithm)
- $\lambda = -1$: (Inverse plus 1)

```
food %>% autoplot(box_cox(Turnover, 1/3)) +
  labs(y = "Box-Cox transformed turnover")
```

```
food %>%
  features(Turnover, features = guerrero)

## # A tibble: 1 x 1
## lambda_guerrero
## <dbl>
## 1 0.0524
```

```
food %>%
features(Turnover, features = guerrero)
```

```
## # A tibble: 1 x 1
## lambda_guerrero
## <dbl>
## 1 0.0524
```

- This attempts to balance the seasonal fluctuations and random variation across the series.
- Always check the results.
- A low value of λ can give extremely large prediction intervals.

Transformations

- Often no transformation needed.
- Simple transformations are easier to explain and work well enough.
- Transformations can have very large effect on PI.
- If the data contains zeros, then don't take logs.
- If some data are negative, no power transformation is possible unless a constant is added to all values.
- Choosing logs is a simple way to force forecasts to be positive
- Transformations must be reversed to obtain forecasts on the original scale. (Handled automatically by fable.)

Lab Session 7

- For the following series, find an appropriate transformation in order to stabilise the variance.
 - United States GDP from global_economy
 - Slaughter of Victorian "Bulls, bullocks and steers" in aus_livestock
 - Gas production from aus_production
 - Tobacco from aus_production
 - Economy class passengers between Melbourne and Sydney from ansett
 - Victorian Electricity Demand from vic_elec.
- Why is a Box-Cox transformation unhelpful for the expsmooth::cangas data?
