- 2 Lab Session 8
- 3 Seasonal ARIMA models
- 4 Lab Session 9

AR: autoregressive (lagged observations as inputs)

I: integrated (differencing to make series stationary)

MA: moving average (lagged errors as inputs)

AR: autoregressive (lagged observations as inputs)

I: integrated (differencing to make series stationary)

MA: moving average (lagged errors as inputs)

An ARIMA model is rarely interpretable in terms of visible data structures like trend and seasonality. But it can capture a huge range of time series patterns.

# **Stationarity**

#### **Definition**

If  $\{y_t\}$  is a stationary time series, then for all s, the distribution of  $(y_t, \ldots, y_{t+s})$  does not depend on t.

5

# **Stationarity**

#### **Definition**

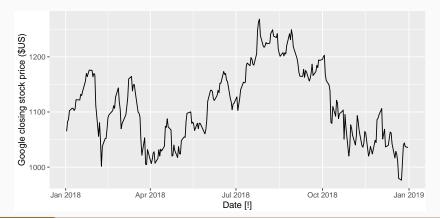

If  $\{y_t\}$  is a stationary time series, then for all s, the distribution of  $(y_t, \ldots, y_{t+s})$  does not depend on t.

#### A stationary series is:

- roughly horizontal
- constant variance
- no patterns predictable in the long-term

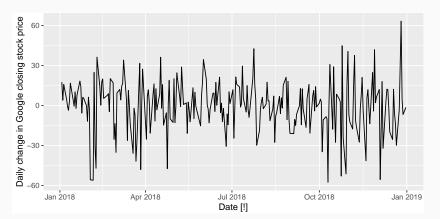

## **Stationary?**

```
gafa_stock %>%
  filter(Symbol == "G00G", year(Date) == 2018) %>%
  autoplot(Close) +
   ylab("Google closing stock price ($US)")
```

## **Stationary?**

```
gafa_stock %>%
  filter(Symbol == "G00G", year(Date) == 2018) %>%
  autoplot(difference(Close)) +
    ylab("Daily change in Google closing stock price")
```

# **Differencing**

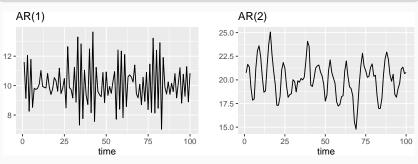

- Differencing helps to **stabilize the mean**.
- The differenced series is the change between each observation in the original series.
- Occasionally the differenced data will not appear stationary and it may be necessary to difference the data a second time.
- In practice, it is almost never necessary to go beyond second-order differences.

# **Autoregressive models**

#### **Autoregressive (AR) models:**

$$y_t = c + \phi_1 y_{t-1} + \phi_2 y_{t-2} + \cdots + \phi_p y_{t-p} + \varepsilon_t,$$

where  $\varepsilon_t$  is white noise. This is a multiple regression with **lagged values** of  $y_t$  as predictors.

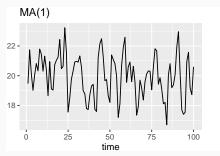

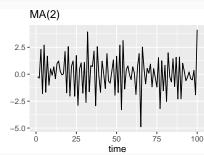

Cyclic behaviour is possible when p > 2.

# Moving Average (MA) models

#### Moving Average (MA) models:

 $y_t = c + \varepsilon_t + \theta_1 \varepsilon_{t-1} + \theta_2 \varepsilon_{t-2} + \cdots + \theta_q \varepsilon_{t-q},$ where  $\varepsilon_t$  is white noise. This is a multiple regression with **lagged** *errors* as predictors. Don't confuse this with moving average smoothing!

## **Autoregressive Moving Average models:**

$$y_{t} = c + \phi_{1}y_{t-1} + \dots + \phi_{p}y_{t-p}$$
$$+ \theta_{1}\varepsilon_{t-1} + \dots + \theta_{q}\varepsilon_{t-q} + \varepsilon_{t}.$$

#### **Autoregressive Moving Average models:**

$$y_{t} = c + \phi_{1}y_{t-1} + \dots + \phi_{p}y_{t-p}$$
$$+ \theta_{1}\varepsilon_{t-1} + \dots + \theta_{q}\varepsilon_{t-q} + \varepsilon_{t}.$$

Predictors include both lagged values of  $y_t$  and lagged errors.

#### **Autoregressive Moving Average models:**

$$y_{t} = c + \phi_{1}y_{t-1} + \dots + \phi_{p}y_{t-p}$$
$$+ \theta_{1}\varepsilon_{t-1} + \dots + \theta_{q}\varepsilon_{t-q} + \varepsilon_{t}.$$

Predictors include both lagged values of y<sub>t</sub> and lagged errors.

#### **Autoregressive Integrated Moving Average models**

- Combine ARMA model with differencing.
- d-differenced series follows an ARMA model.
- Need to choose *p*, *d*, *q* and whether or not to include *c*.

#### ARIMA(p, d, q) model

AR: p = order of the autoregressive part

I: d =degree of first differencing involved

MA: q = order of the moving average part.

- White noise model: ARIMA(0,0,0)
- Random walk: ARIMA(0,1,0) with no constant
- Random walk with drift: ARIMA(0,1,0) with const.
- $\blacksquare$  AR(p): ARIMA(p,0,0)
- $\blacksquare$  MA(q): ARIMA(0,0,q)

```
fit <- global_economy %>%
  model(arima = ARIMA(Population))
fit

# **Understanding ARIMA models**

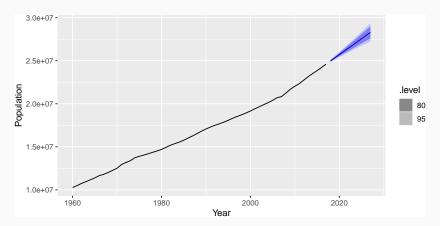

- If c = 0 and d = 0, the long-term forecasts will go to zero.
- If c = 0 and d = 1, the long-term forecasts will go to a non-zero constant.
- If c = 0 and d = 2, the long-term forecasts will follow a straight line.
- If  $c \neq 0$  and d = 0, the long-term forecasts will go to the mean of the data.
- If  $c \neq 0$  and d = 1, the long-term forecasts will follow a straight line.
- If  $c \neq 0$  and d = 2, the long-term forecasts will follow a quadratic trend.

# **Understanding ARIMA models**

#### Forecast variance and d

- The higher the value of *d*, the more rapidly the prediction intervals increase in size.
- For d = 0, the long-term forecast standard deviation will go to the standard deviation of the historical data.

```
fit %>% forecast(h=10) %>%
  filter(Country=="Australia") %>%
  autoplot(global_economy)
```

## Hyndman and Khandakar (JSS, 2008) algorithm:

- Select no. differences d via KPSS test.
- Select *p*, *q* and inclusion of *c* by minimising AICc.
- Use stepwise search to traverse model space.

## Hyndman and Khandakar (JSS, 2008) algorithm:

- Select no. differences d via KPSS test.
- Select p, q and inclusion of c by minimising AICc.
- Use stepwise search to traverse model space.

AICc = 
$$-2 \log(L) + 2(p+q+k+1) \left[ 1 + \frac{(p+q+k+2)}{T-p-q-k-2} \right]$$
. where  $L$  is the maximised likelihood fitted to the differenced data,  $k = 1$  if  $c \neq 0$  and  $k = 0$  otherwise.

## Hyndman and Khandakar (JSS, 2008) algorithm:

- Select no. differences d via KPSS test.
- Select *p*, *q* and inclusion of *c* by minimising AICc.
- Use stepwise search to traverse model space.

AICc = 
$$-2 \log(L) + 2(p+q+k+1) \left[ 1 + \frac{(p+q+k+2)}{T-p-q-k-2} \right]$$
. where *L* is the maximised likelihood fitted to the differenced data,  $k = 1$  if  $c \neq 0$  and  $k = 0$  otherwise.

Note: Can't compare AICc for different values of d.

**Step1:** Select current model (with smallest AICc) from:

ARIMA(2, d, 2)

ARIMA(0, d, 0)

ARIMA(1, d, 0)

ARIMA(0, d, 1)

```
Step1: Select current model (with smallest AICc) from: ARIMA(2, d, 2) ARIMA(0, d, 0) ARIMA(1, d, 0) ARIMA(0, d, 1)
```

- **Step 2:** Consider variations of current model:
  - vary one of p, q, from current model by  $\pm 1$ ;
  - p, q both vary from current model by  $\pm 1$ ;
  - Include/exclude c from current model.

Model with lowest AICc becomes current model.

```
Step1: Select current model (with smallest AICc) from:

ARIMA(2, d, 2)

ARIMA(0, d, 0)

ARIMA(1, d, 0)

ARIMA(0, d, 1)
```

- **Step 2:** Consider variations of current model:
  - vary one of p, q, from current model by  $\pm 1$ ;
  - p, q both vary from current model by  $\pm 1$ ;
  - Include/exclude *c* from current model.

Model with lowest AICc becomes current model.

Repeat Step 2 until no lower AICc can be found.

## **Outline**

- 1 ARIMA models
- 2 Lab Session 8
  - 3 Seasonal ARIMA models
- 4 Lab Session 9

#### **Lab Session 8**

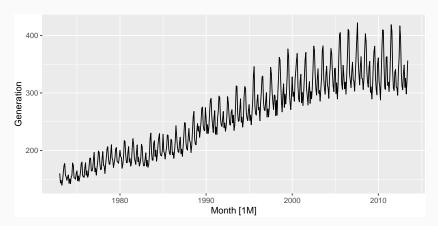

For the United States GDP data (from global\_economy):

- Fit a suitable ARIMA model for the logged data.
- Produce forecasts of your fitted model. Do the forecasts look reasonable?

## sigma^2 estimated as 0.0006841: log likelihood=1047
## AIC=-2082 AICc=-2082
                           BIC=-2057
```

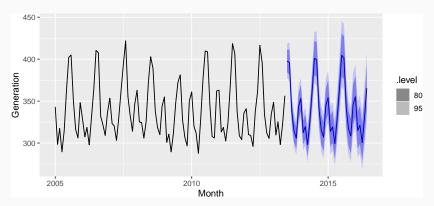

# **Example: US electricity production**

```
usmelec %>%
model(arima = ARIMA(log(Generation))) %>%
forecast(h="3 years") %>%
autoplot(usmelec)
```

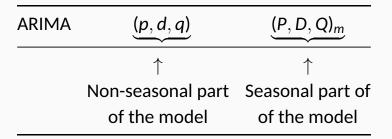

# **Example: US electricity production**

```
usmelec %>%
model(arima = ARIMA(log(Generation))) %>%
forecast(h="3 years") %>%
autoplot(filter_index(usmelec, 2005 ~ .))
```

#### **Seasonal ARIMA models**

- $\blacksquare$  m = number of observations per year.
- d first differences, D seasonal differences
- p AR lags, q MA lags
- *P* seasonal AR lags, *Q* seasonal MA lags

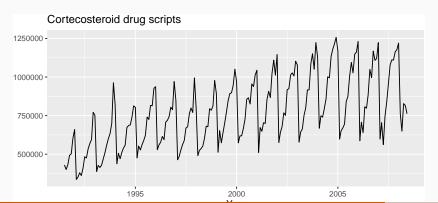

Seasonal and non-seasonal terms combine multiplicatively

#### **Common ARIMA models**

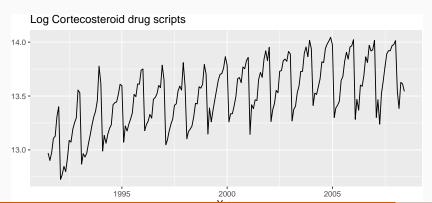

The US Census Bureau uses the following models most often:

ARIMA(0,1,1)(0,1,1) <sub>m</sub>	with log transformation
$ARIMA(0,1,2)(0,1,1)_m$	with log transformation
$ARIMA(2,1,0)(0,1,1)_m$	with log transformation
$ARIMA(0,2,2)(0,1,1)_m$	with log transformation
$ARIMA(2,1,2)(0,1,1)_m$	with no transformation

```

- 4 Lab Session 9

#### **Lab Session 9**

For the Australian tourism data (from tourism):

- Fit a suitable ARIMA model for all data.
- Produce forecasts of your fitted models.
- Check the forecasts for the "Snowy Mountains" and "Melbourne" regions. Do they look reasonable?
